Plastic Containers for Avocado Nursery Trees

R. M. BURNS

Plastic containers for avocado nursery trees are relatively new in California, but nurserymen are showing increasing interest in them. One of the most popular avocado nursery containers for many years has been the tarpaper cylinder made from heavy roofing paper. These tarpaper containers have two main shortcomings: the relatively high labor cost of cutting and stapling; and frequent disintegration.

Polyethylene containers have been used for a number of years to propagate such tropical plants as coffee, rubber, and cocoa. In these instances the plastic container is usually a long polyethylene bag that is open at the top but closed at the bottom, with holes for drainage.

One of the first uses of plastic containers for avocados was in a nursery near Teziutlan, Mexico in June 1963. These containers were made from 8 mil black polyethylene tubing. This was cut with a regular paper cutter into 14-inch lengths. When flat, they were 10 inches wide, and when full of soil, made a container approximately 6 inches in
diameter. The nurseryman was planning to reuse the plastic and he demonstrated how the container could be slipped off without being cut and without disturbing the soil and roots of the tree.

Two cooperative trials were started in California in November 1963, one at the W. E. Frey Nursery in Escondido and the other at the W. H. Brokaw Nursery in Ventura. In each of these trials 200 containers, 14 inches long, were cut from a long length of 8 mil black polyethylene tubing. The containers when filled were 6 inches in diameter. The material for each container cost about 15 cents.

Seed germination rates and seedling measurements in comparable numbers of plastic and tarpaper containers were made periodically in both trials. There were some differences in germination and growth, but these were not significant.

A commercially acceptable number of seedlings in both types of containers at both nurseries were budded and were eventually sold together at the normal planting time.

Subsequent to starting the trials, avocado nursery trees were observed growing in plastic bags in the Homestead area of Florida, and also tea cuttings grown experimentally at the University of Florida at Gainesville. The tea cuttings were in relatively long, narrow plastic bags containing a mixture of peat and perlite. The bags were placed upright in wooden lettuce crates to provide support and to facilitate easier movement. One of the first problems with polyethylene containers was that they are not rigid as tarpaper containers, which meant special handling is necessary when filled with soil. W. H. Brokaw has developed a metal bin and form which allows simultaneous filling of six plastic containers. Getting the proper soil mix to eliminate sagging of the container when filled is another problem, as well as determining the proper amount of tamping when filling. Some avocado nurserymen have also experienced some problems with excess moisture at the bottom of plastic bags indicating that the number of holes in the

bottom, and irrigation techniques, are very important with this container.
